The low elevation and gradual slope of south Florida makes its ecosystems and cultural resources particularly vulnerable to increases in water level. Prairies convert to marsh.

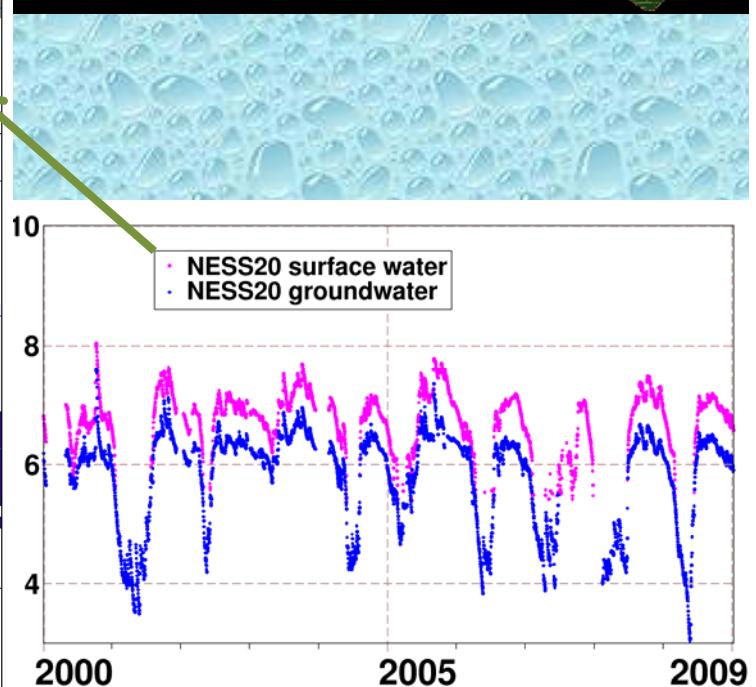

Further lowering of water levels due to alterations in flows, rainfall and evapotranspiration will continue to change wetlands to upland environments.

# Soil Thickness and Water Levels

South Florida Natural Resources Center

Data Sources: REMAP, NPS and USGS

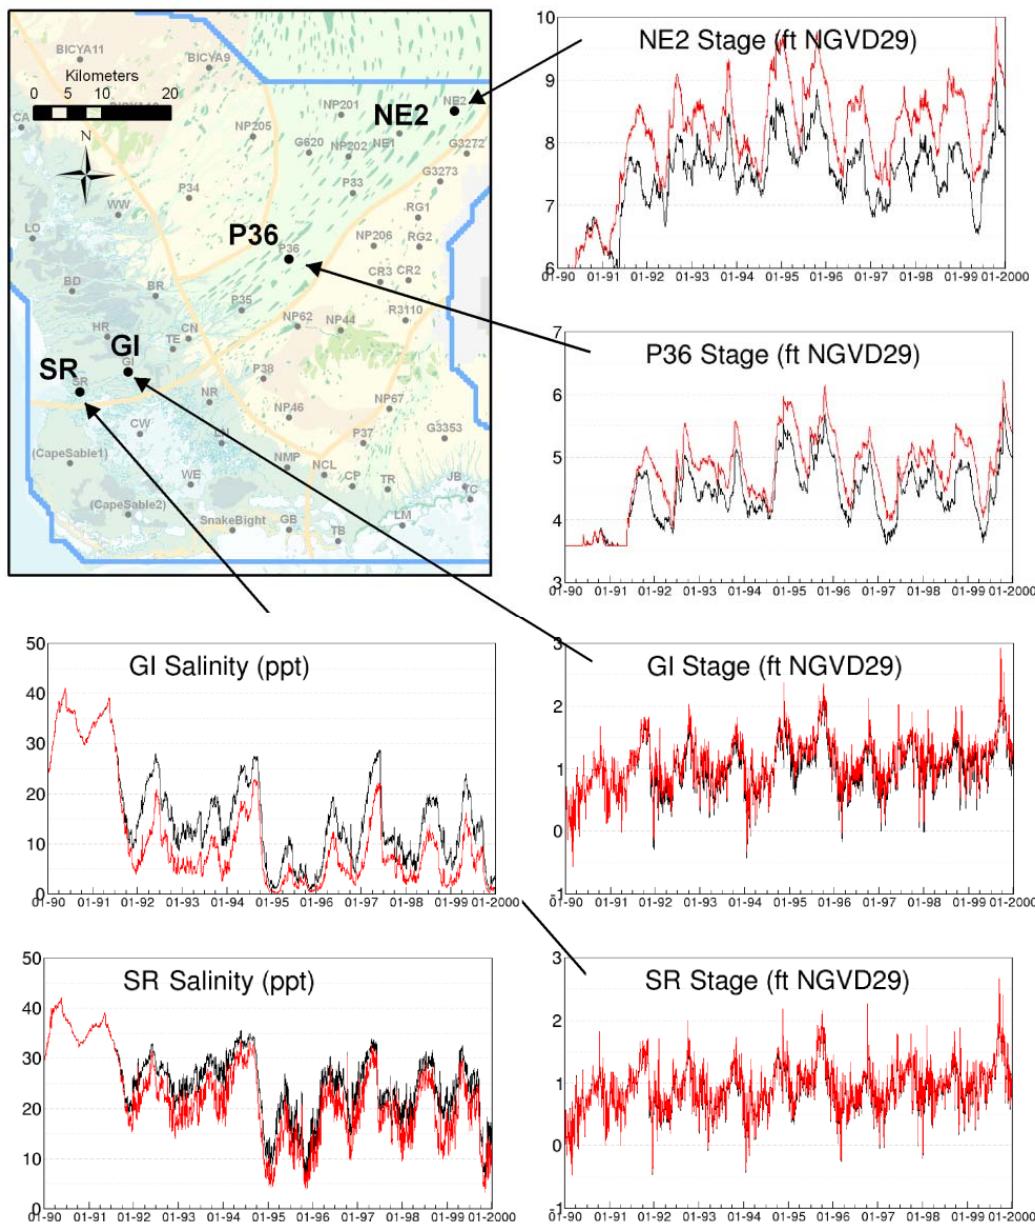

Mangrove peat underlies the coastal zone.

Sawgrass/Water Lily peat in Shark Slough and Taylor Slough. Distinct surface water and groundwater levels caused by low vertical permeability of the peat.

# TIME model, stages and salinity

South Florida Natural Resources Center

TIME output with SFWMM (2x2)  
flows as input along Tamiami Trail.

Current (Alt7r5e) in black  
Future (Cerp0) in red

The stages are significantly  
different in upper Shark Slough.

Flows are the driving force to  
lower salinities.

# Potential Everglades Ecological Effects

South Florida Natural Resources Center

**Tolerances to changes in, for example, temperature, hydroperiods, or sea level may be exceeded for some species.**

**Species depend on timing of physical events such as wading bird nesting during periods of water recession.**

**Habitat change. Succession to new vegetation communities.**

Breeding season March-August

Nests constructed of muhly grass and sawgrass.

Situated 14 cm off the ground (range 7 to 27 cm).

# Vegetation Changes

South Florida Natural Resources Center

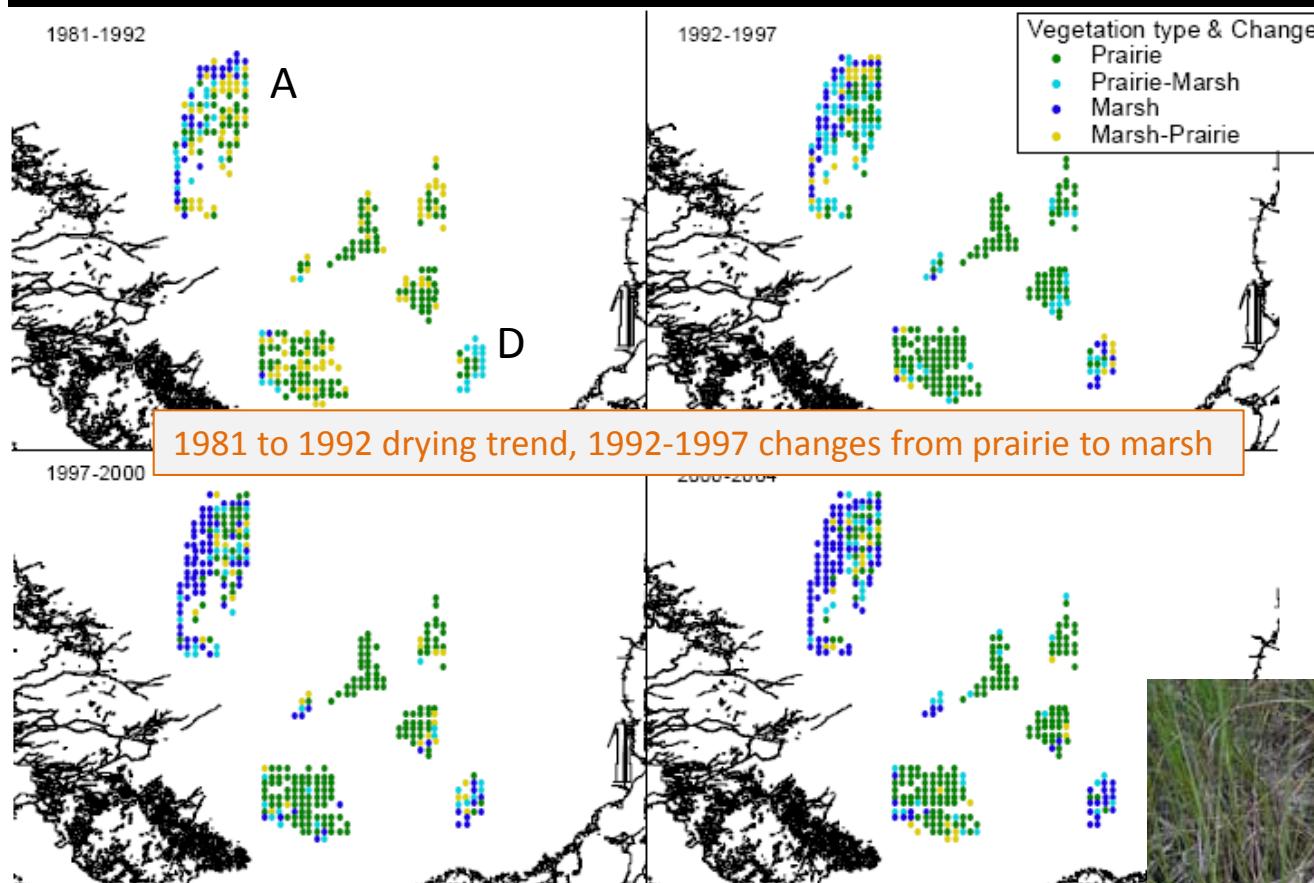

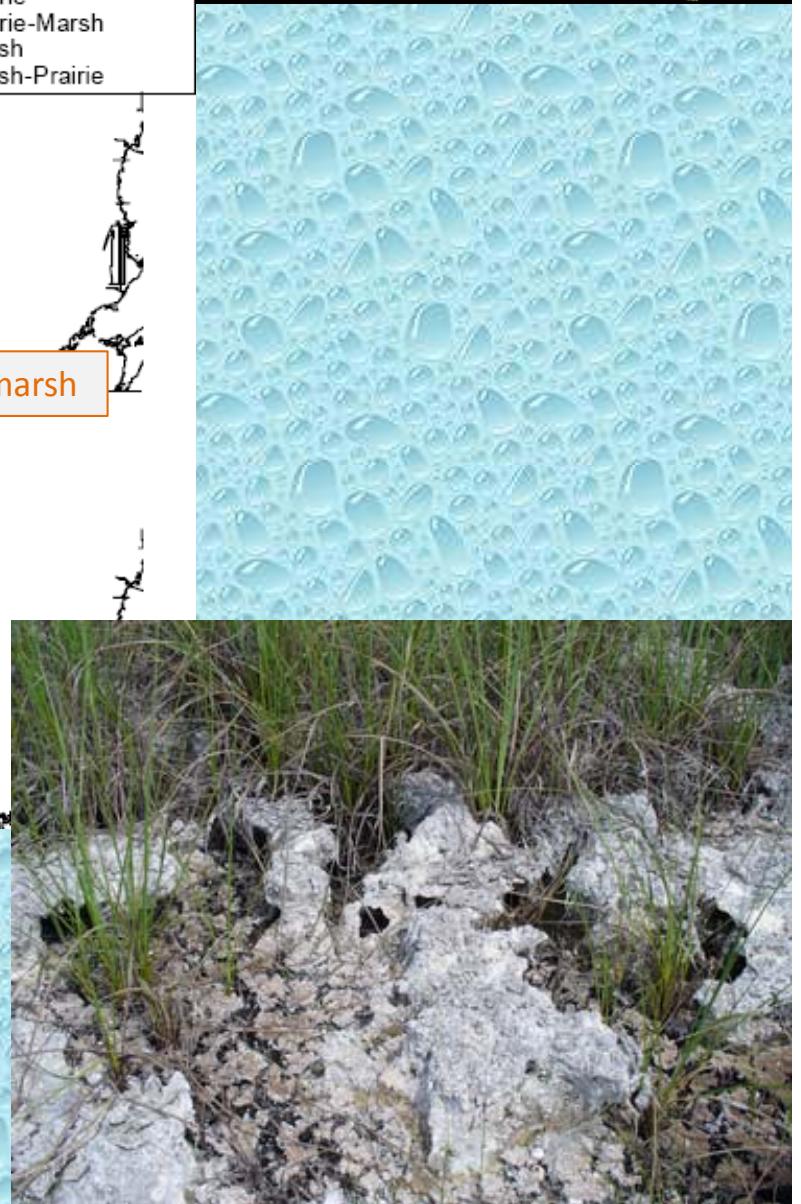

Image Source: Ross et al. 2004, annual report on habitat of CSSS

**Areas A and D changed from prairie to marsh**

**Hydroperiods:**

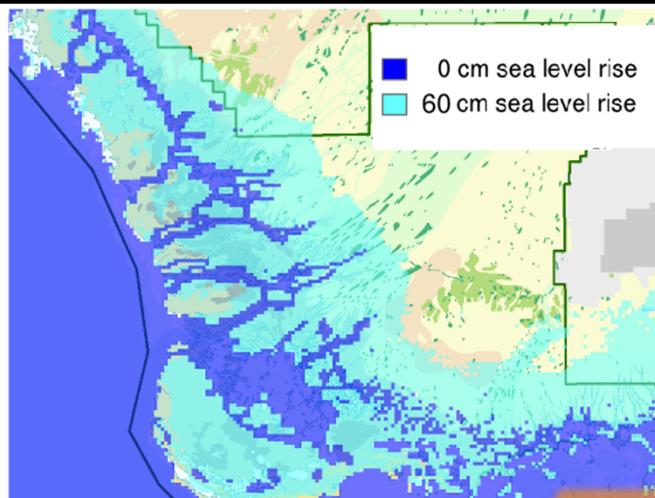

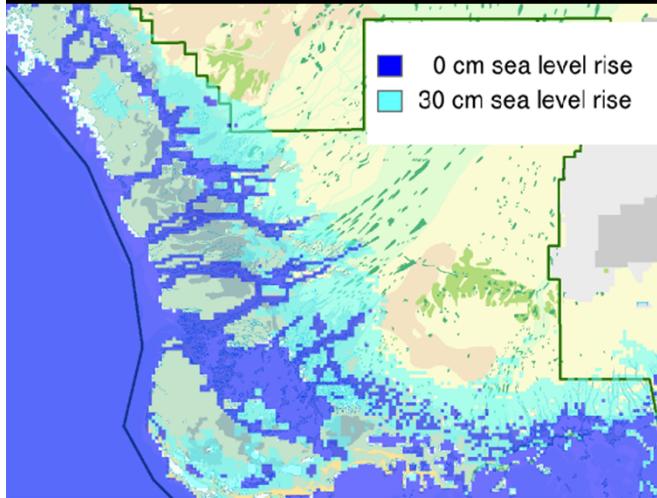

**Wet prairie 199 days**

**Marsh 246 days**

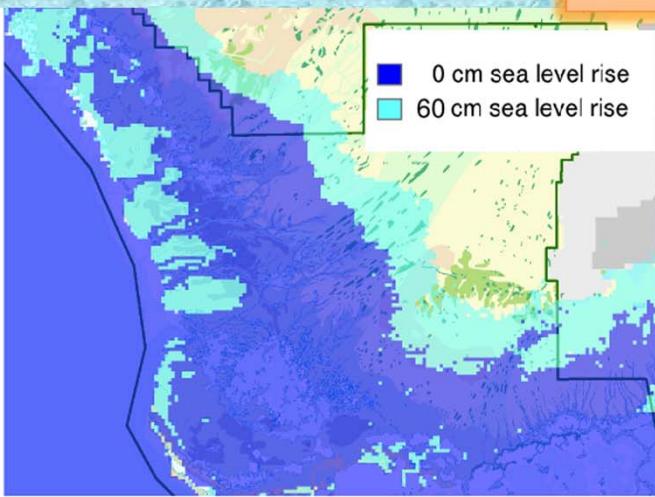

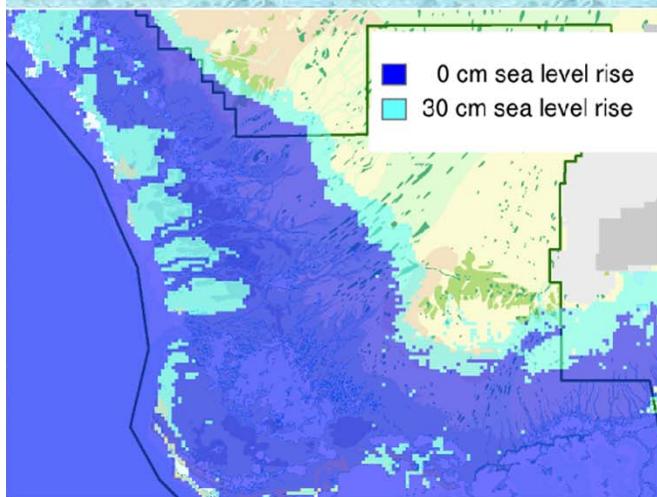

# Sea Level Rise

South Florida Natural Resources Center

Minimum, -0.45 m below mean

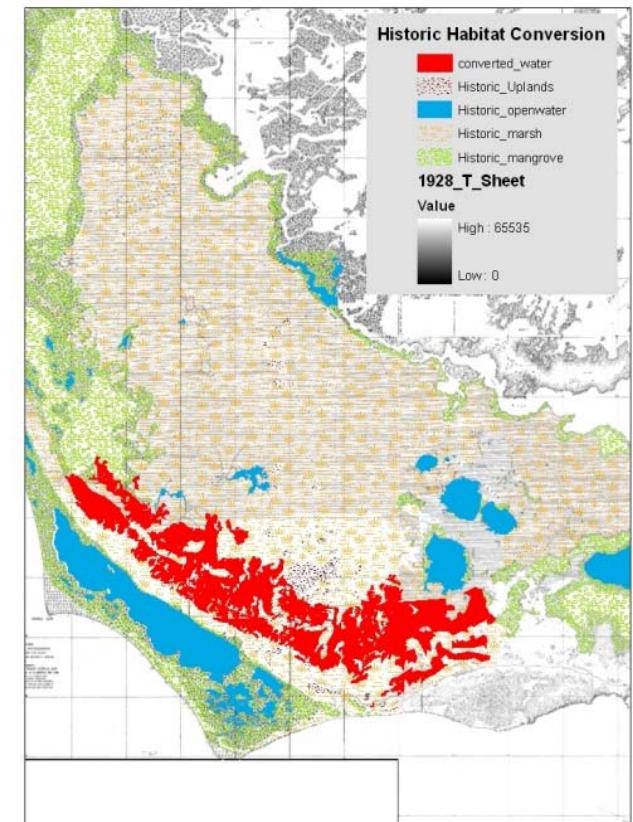

Inundation increase as a result of SLR, for the average 0.5 m tidal range in the Gulf

Maximum, 0.05 m above mean

## With Sea Level Rise, Why Restore the Everglades?

1. Species may be able to adapt\* if given time. Restoration provides freshwater head to offset sea level rise saline transgressions.
2. The Everglades ecosystems will change, but abrupt changes are likely to be less stable and diverse than gradual change.

- \*Adapt:
1. change or phenotypic plasticity
  2. Protect or create corridors & stepping stone habitat
  3. Assisted propagation and adaptive breeding
  4. Assisted Migration
  5. Seed Banks & captive populations
